WIFI_EN <-> GPIO4<->GPIO1_4 GPIO로 설정

"arch/arm/boot/dts/imx6qdl-sabresd.dtsi"에 추가

```
mango_wifi_reset: mango-wifi-reset {
    compatible = "gpio-reset";
    reset-gpios = <&gpio1 5 GPIO_ACTIVE_LOW>;
    reset-delay-us = <100000>;
    initially-in-reset;
    #reset-cells = <0>;
};
```

```
&usdhc2 {
    pinctrl-names = "default";
    pinctrl-0 = <&pinctrl_usdhc2_1>;
#if 0
    cd-gpios = <&gpio2 2 0>;
    wp-gpios = <&gpio2 3 0>;
#endif
    resets = <&mango_wifi_reset>;
    enable-gpio = <&gpio1 4 0>;
    no-1-8-v;
    keep-power-in-suspend;
    enable-sdio-wakeup;
    status = "okay";
};
```

SDIO 2번 채널에 WiFi 모듈을 연결을 할 수 있도록 회로가 되어 있습니다. "drivers/mmc/host/sdhci-esdhc-imx.c" 파일에 추가

```
sdhci_esdhc_imx_probe_dt(struct platform_device *pdev,
                          struct esdhc_platform_data *boarddata) 함수에 내용 추가
device_reset(&pdev->dev);
        enable qpio = of qet named qpio(np, "enable-qpio", 0);
        if (gpio_is_valid(enable_gpio))
        {
                  status = devm gpio request one(&pdev->dev,enable gpio,
                                                  GPIOF OUT INIT HIGH, NULL);
             if(status < 0)
             {
            dev err(&pdev->dev, "Wifi EN Request Fail status %d₩n"
                                                                   ,status);
                 return status;
                 }
        }
        return 0;
```

커널 컴파일 후 커널 로그에서 아래와 같이 디버깅 메시지가 나오면,

인식이 된 것입니다.
